

**MALE INVOLVEMENT IN FAMILY
PLANNING – A RECENT APPROACH – NO
SCALPEL VASECTOMY: A STUDY AT
KILPAUK MEDICAL COLLEGE HOSPITAL,
CHENNAI.**

Dissertation submitted to

The Tamil Nadu Dr.M.G.R. Medical University

for

M.Ch. DEGREE EXAMINATION

BRANCH – IV (UROLOGY)

**THE TAMIL NADU DR.M.G.R. MEDICAL UNIVERSITY
CHENNAI, INDIA.**

AUGUST 2011

DECLARATION

I **Dr. G. LATHA** solemnly declare that this dissertation titled **“MALE INVOLVEMENT IN FAMILY PLANNING – A RECENT APPROACH – NO SCALPEL VASECTOMY: A STUDY AT KILPAUK MEDICAL COLLEGE HOSPITAL, CHENNAI”** is a bonafide work done by me in the Department of Urology, Govt. Kilpauk Medical College and Hospital and Govt. Royapettah Hospital under the guidance and supervision of my Professor **PROF. V. SELVARAJ M.Ch.** Professor, Department of Urology, Govt. Kilpauk Medical College and Hospital and **Prof. C.ILAMPARUTHI M.Ch., DNB.,** Prof. Department of Urology Govt. Royapettah Hospital.

This Dissertation is submitted to the Tamilnadu Dr. M.G.R. Medical University, Chennai towards M.Ch. Branch IV, Urology degree examination.

Chennai

Date:

Dr. G. LATHA

CERTIFICATE

This is to certify that this dissertation **MALE INVOLVEMENT
IN FAMILY PLANNING – A RECENT APPROACH – NO
SCALPEL VASECTOMY: A STUDY AT KILPAUK MEDICAL
COLLEGE HOSPITAL, CHENNAI** is the bonafide work done by
_____ under the guidance and
supervision in the **Department Of Urology, Kilpauk Medical College,
Kilpauk, and Govt. Royapettah Hospital, submitted for the M.Ch.
Degree Examination Branch – IV (Urology), to be held in August
2011, by the The Tamilnadu Dr.M.G.R. Medical University,
Chennai, India.**

Prof. Dr. V. Selvaraj M.Ch.,
Department of Urology,
Kilpauk Medical College Hospital,
Chennai-10.

Prof. Dr. C. Ilamparuthi M.Ch., DNB,
Department of Urology,
Govt. Royapettah Hospital,
Chennai-14.

Dean
Govt. Kilpauk Medical College
Chennai – 600 010.

ACKNOWLEDGEMENT

I thank **Dr. S.GEETHA LAKSHMI M.D.**, The Dean, Kilpauk Medical College for granting me permission to do my Dissertation.

I extend my respectful thanks to **Dr. K.THIYAGARAJAN M.Ch., DNB., SUPERINTENDENT, GRH AND Dr. R. SUKUMAR M.D., MEDICAL SUPERINTENDENT, KMCH** for their kind guidance, help and encouragement.

I thank **PROF. VAIRAVEL D.G.O., M.Ch. KMC** for his kind guidance and advice.

I thank **PROF. V. SELVARAJ M.Ch. STATE TRAINER FOR NSV and PROF UROLOGY, KMCH, CHENNAI** for his constant guidance and encouragement throughout the period of this study and without his help this study would not have come through.

I thank **PROF. C.ILAMPARUTHI M.Ch., DNB.**, for his encouragement and help.

I also extend my thanks to my Assistant Professors **Dr. P.LEELA KRISHNA M.Ch, Dr. R.JAYAGANESH M.Ch,**
Dr. G.SIVASANKAR M.Ch, Dr. A.SENTHILVEL M.Ch,

Dr T.SRIKALA PRASAD M.Ch, for their timely help and proper guidance.

I am grateful to all the patients who have participated in this study.

I thank my husband and my children for their kind co-operation.

Above all I owe my thanks to the Almighty for the successful completion of my study.

INTRODUCTION

Vasectomy is a safe and effective method of contraception. Worldwide, however, far fewer vasectomies are performed than female sterilizations by tubal ligation, even though vasectomy is less expensive and less morbidity than tubal ligation.

This apparent underutilization of a safe procedure is caused in part, by concerns of men and their partners. Some men fear pain and complications (1). Others falsely equate vasectomy with castration or loss of masculinity. Women think that if vasectomy done that may cause loss working energy because male partner are the working person in their family.

Although Vasectomy should be considered a permanent procedure, nearly 6% of men undergo vasectomy ultimately desire for reversal.

The No-Scalpel Vasectomy project is being implemented in this country through MINISTRY OF HEALTH AND FAMILY WELFARE to help men adopt male sterilization and thus promote male participation in the Family Welfare program(2). The active role of no-scalpel vasectomy by PROF R.C.M.KAZA, MASTER TRAINER, NSV, GOVT. OF INDIA AND PROF OF SURGERY, MOULANA AZAD MEDICAL COLLEGE HOSPITAL, NEW DELHI(1).

HISTORICAL REVIEW

In 1897, Van Meter suggested vasectomy for male sterilization to eradicate hereditary disease from human family.

The first eugenic sterilization was performed by Dr. Harry Sharp, chief physician of the Indiana State Reformatory. The inmate named Clawson insisted on castration to stop excessive masturbation. Sharp performed vasectomy on October 12, 1899(3).

In 1909, William Belfield, professor of surgery at Rush Medical College, wrote about married men who chose vasectomy rather than criminal abortion to prevent the transmission of insanity and syphilis to the offspring.

Vasectomy as a contraceptive procedure for family planning was successfully introduced to control rapidly growing population in developing Asian countries. India launched a massive program and became the first country in the world to make it an official Government Policy in 1952(4). Vasectomy reached a new level during India's Emergency Period (1975- 1977). Over these 2 years, a total of 6.2 million vasectomies performed in 1976. When the Emergency ended in 1977, the Government was preparing the laws to make small families compulsory.

Technical evolution of vasectomy

Early vasectomies performed via inguinal approach. First modification was the English Method, selects the scrotal region as the site of operation. In 1955, Jhaver introduced the single incision approach for bilateral vasectomy. The possibility of spontaneous vasal reanastomosis, which was clinically Harrison observed in 1900, and was confirmed by Rolnick(5). Besides the ligation of the cut vasal ends, Strode(1937) first attempted a fascial interposition between the ligated end of vas deferens. In 1966, Schmidt introduced the fulgration of the vassal lumen with electrocautery.

Jhaver started to use tantalum metal clip one on each side instead of ligature, whereas Moss advocated two tantalum clips on each side of divided end for occlusion(28).

In 1973, the no scalpel vasectomy technique developed in China by Dr. Shan Quang Li and associates(24). The no scalpel vasectomy has rapidly gained popularity among the surgeons and patients because of short operating time, less tissue injury, less postoperative swelling and pain and lower complication rate.

In 2002, the Vasa clip, a small implantable biocompatible lock made of a medical- grade polymer(7). But it fails in the market due to cost. Recently the feasibility of thermal occlusion of the vas deferens with noninvasive, transcutaneous HIFU has been demonstrated on animal models(33).

Vasectomy reversal

Most surgeons who adopted these techniques borrowed the instruments from ophthalmologists, since they had been doing microsurgery for years. Many companies now manufacture a variety of instruments for urologic and plastic microsurgery. Suture manufacturers have likewise responded to the needs of the microsurgeon with specific sutures and needles that make the performance of these often tedious procedures less burdensome.

AIM OF STUDY

1. To Study the Advantage of No Scalpel Vasectomy as permanent sterilization procedure in males.
2. To study the utility of No Scalpel Vasectomy in mass Sterilization program according to National Family Health Survey II Data
3. To analyze the efficacy of placing the cut vas in different fascial planes.
4. To analyze the outcome of surgical procedure.
5. To study the role of vasectomy reversal.

MATERIAL AND METHODS

1. STUDY GROUP:

Study group are outpatients in the Kilpauk Medical College Hospital, Chennai.

All the patients attending to the centre for voluntary permanent sterilization were counseled about No Scalpel Vasectomy. After getting informed consent surgery performed.

2. STUDY DESIGN:

Cross Sectional Study.

3. STUDY PERIOD: From September 2008 to March 2011.

4. METHODS :

Under Local Anesthesia, No Scalpel Vasectomy done for the all patients. After vasectomy, all the patients were advised to follow-up after three months. Vasectomy specimen sent for histo pathological examination. Semen analysis was done after three months.

5. INCLUSION CRITERIA:

Age group less than 60 year

Married and have at least one child.

6. EXCLUSION CRITERIA:

Inflammatory pathology in scrotum and testis.

Comorbid illness

Associated Hydrocele, Inguinal Hernia.

REVIEW OF LITERATURE

No-scalpel vasectomy (NSV) was developed in China in 1974 by Dr S.Q. Li at the Chongking Family Planning Institute(24). It was introduced to the United States in 1988. Dr Marc Goldstein witnessed the operation in China, and then arranged a world team, under the direction of the World Health Organization and AVSC (association for voluntary surgical contraception) International, to investigate it.

A randomized study of 1203 vasectomies performed in 1 day at the King's Birthday Vasectomy Festival in Bangkok revealed an eightfold lower incidence of bleeding and infection with the NSV group.

Vasectomy is a safe and effective method of permanent contraception. In the United States, it is employed by nearly 11% of all married couples and performed on approximately 500,000 men per year, more than any other urologic surgical procedure(8).

Realization of the need to focus on men had resulted at the 1994 International Conference on Population and Development (ICPD) in Cairo as well as at the 1995 World Conference on Women in Beijing(9). The Program of Action endorsed at the Cairo conference calls for the need to recognize men as equal partners with women in all matters

relating to reproductive health and family planning. Taking the cue from the ICPD, the National Population Policy of India, 2000 recognizes men as the under-served population (10). It sees the exclusion of the men from the family planning programs as a shortfall of the past for in a patriarchal society like India men play the critical role in all matters relating to the family. Therefore it aims at focusing attention on men in the information and education campaigns and to promote the small family norm (11). It also aims at re-popularizing male contraception especially no-scalpel vasectomy as a simple and painless procedure, more convenient and acceptable to men (MOHFW, 2000).

The movement to involve men in reproductive health has many names, including men's participation, men's responsibility, male motivation, male involvement, men as partners and men and reproductive health (Ghosh, 1999)(12). They all broadly refer to a complex process of social and behavioral change that is needed for men to play more responsible roles in reproductive health (Population Reports, 1998). The involvement of men in reproductive health encompasses activities at many levels. It involves planning the number of offspring and their structure with the partner, approving of contraceptive use and using them, taking special care of wives and partners when they are pregnant, seeking

skilled health care, taking care after the baby is born, and being responsible fathers(13).

In this paper we analyze the various social, economic and demographic and behavioral factors that influence contraceptive use by men in India. For the purpose we have selected the states from north and south of India given the north -south dichotomy that exists as regards to various social, economic and demographic and autonomy aspects (Dyson and Moore, 1983).

No-scalpel vasectomy technique

The no-scalpel technique requires two instruments specially designed by Dr. Li Shunqiang(27).

The extra cutaneous ring forceps or Vas fixation clamp is a type of clamp used to fix the vas deferens. Throughout the operation, the surgeon uses the ringed tip of this instrument to encircle and grasp the vas, without injuring the skin. The instrument comes in three sizes: 3.0mm, 3.5mm, and 4.0mm.

The Vas dissecting forceps is similar to a curved mosquito hemostat, except the tips are sharply pointed. It is used to puncture the

scrotal skin, to spread the tissues, to dissect the sheath, and to deliver the vas deferens. The dissecting forceps can also be used to grasp the vas while ligature or cautery is applied for occlusion. It can be used to control bleeding also.

Additional instruments and supplies for no-scalpel vasectomy

- Soap and water or antiseptic agents • Alcohol rinse

- Sterile gloves • Antiseptic solution for cleaning the operative area
- Sterile drapes • 10-cc syringe with a 1 1/2-inch, 23-gauge needle
- 1% or 2% lidocaine without epinephrine
- Supplies for vasal occlusion according to the surgeon's preference (eg: a cautery unit; chromic catgut or nonabsorbable silk or cotton for ligation)
- Sterile gauze • Adhesive tape or Band-Aid for dressing the wound
- Scrotal support for the man to wear after the procedure

Traditional vasectomy is usually performed under a field block. Local anesthetic is infiltrated into multiple tissue planes, swelling the tissue, so the vas must be held firm.

Three finger technique

No-scalpel vasectomy is typically performed as an outpatient procedure with use of local anesthetics. The choice of local anesthetic is of 1% plain lidocaine. The vas deferens is separated from the spermatic cord vessels and manipulated to a superficial position under the scrotal skin.

The vas is firmly trapped between the middle finger, the index finger, and the thumb of the left hand. A small superficial skin wheal is raised with a 1.5-inch 23-gauge needle. The needle is then advanced within the perivasal sheath, and a small amount of local anesthetic is injected around the vas without moving the needle in and out.

This produces a vasal nerve block and minimizes edema at the actual vasectomy site. The contralateral vas deferens may be anesthetized at the same time or just before that side is addressed.

The ring-tipped fixation clamp is grasped with the right hand and opened while pressing downward, stretching the scrotal skin tightly over

the vas and locking the vas within the clamp. The ring clamp is placed in the left hand and the trapped vas is elevated with the left index finger, tightening the scrotal skin over the vas. A sharp-pointed, curved vas dissecting forceps (introduced through the same needle puncture hole used for anesthesia) punctures the scrotal skin, vas sheath, and vas wall with one blade of the clamp.

At this point, the surrounding layers are stripped, thus exposing the bare vas. This may be accomplished by using the blades of the sharp dissecting forceps, spreading all layers until the bare vas can be visualized. By using the right blade of the hemostat, the vas wall is skewered from inside the lumen out at a 45-degree angle and the dissecting clamp is rotated laterally 180 degrees. The vas is delivered through the puncture hole while the ringed fixation clamp is released. The

ring clamp is used to secure the delivered vas. The sharp hemostat is used to clean the vasal vessels away from the vas, yielding a clean segment at least 2 cm in length.

The vas is then divided, and occlusion is effected by closing the fascia over one end of the cut vas (fascial interposition) to reduce the likelihood of recanalization. After checking for bleeding, use a small hemostat to tag the vasal ends to inspect for any bleeding before returning the vas to the scrotum. The contralateral vas is then approached in an identical fashion. After both vasa are returned to the scrotum, the puncture hole is pinched for a minute and inspected for bleeding. The puncture hole contracts and is virtually invisible.

Conventional Incisional Technique

After adequate anesthesia is induced, 1-cm bilateral transverse incisions are carried down through the vas sheath until bare vas is exposed. The vas is delivered, and the deferential artery, veins, and accompanying nerves are dissected free of the vas and spared. A small segment is removed, and the ends are occluded by one of the techniques described later in this section.

Variations in vas blocking technique

No Scalpel Vasectomy is only a method of accessing the vas. Methods of blocking the vas vary widely among surgeons. Many are considered acceptable,(3) but a growing body of evidence suggests that the open-ended technique is preferable since it minimizes pain and enhances the potential for successful reversal.(4) Immunohistochemical studies have demonstrated that the mechanical obstruction of the testicular end of the vas results in damage to the testis and epididymis by elevating hydrostatic pressure, generating reactive oxygen species, and initiating specific immune responses.(5) These events result in basement membrane changes in the seminiferous tubules and elsewhere in the testicle. In an experimental rat model these structural changes were absent after open-ended closure when examined 1 year later. (6)

The additional step of interposing fascia between the two cut ends can be combined with either open- or closed-ended techniques to further reduce the chances of failure. In this maneuver, the anterior and posterior aspects of the vas sheath are clipped or sewn together to separate the vas ends into different tissue planes(18).

In the prostatic end of the vas is blocked with intraluminal heat cautery to a depth of 1 cm. The cauterized end is immediately pinched to ensure a solid plug of scar tissue in the lumen. This method avoids clips or sutures applied directly on the vas, which may cause necrosis and distal sloughing, hence possible recanalization. Fascial interposition is accomplished with clips.

For skin closure, the use of a stitch, skin tape, or nothing, has been standard procedure. The use of cyanoacrylate (Dermabond Skin Adhesive) to seal the small puncture is a recent improvement. This method was first employed by Dr Ron Weiss in Ottawa. It allows patients to shower the same day, and no wound care is required.

Percutaneous vasectomy

The Chinese have performed more than 500,000 truly percutaneous vasectomies (and an equal number of vasographies) by chemical occlusion with a combination of cyanoacrylate and phenol(19). After fixation of the vas with the same ring clamp described earlier, the scrotal skin and vas wall are punctured with a 22-gauge needle and the lumen is cannulated with a 24-gauge blunt needle. The needle's position within the vas lumen is confirmed by a series of ingenious tests, with final confirmation obtained by injection of Congo red into the abdominal side of the right vas deferens and methylene blue into the left vas. Injection of 20 μ L of two parts phenol mixed with one part *N*-butyl-2-cyanoacrylate mixture through the 24-gauge blunt-tipped needle occludes the lumen. The patient voids at the termination of the procedure. Excretion of red urine means the left side was missed, and blue urine means the right side was missed; brown urine means both sides were successfully cannulated.

Preferred Methods of Occlusion

Occlusion techniques that result in low rates of recanalization include the following:

1. Removal of a 1-cm segment followed by intraluminal thermal cautery or electrocautery for a distance of 1 cm in each direction, plus application of a medium hemoclip on each end distal to the cauterized segment.
2. Intraluminal cautery plus separation of the vasal ends into different tissue planes with or without removal of a segment.
3. Double medium hemoclips on each end 1 cm apart after removal of a 1-cm segment with or without separation into different tissue planes
4. Fascial interposition with either suture or hemoclips to separate the two vasal segments.

Interposition of fascia between the cut ends, folding back of the vasal ends, and securing one end within the dartos muscle are techniques that have been advocated with the intent of reducing vasectomy failure rates(20).

Open-Ended Vasectomy

Leakage of sperm at the vasectomy site prevents this pressure-induced damage and increase the chances of successful reversal when accurate microsurgical vasovasostomy is performed. If the testicular end

of the vas deferens is not sealed (open-ended technique), a sperm granuloma forms at the vasectomy site and damage to the epididymis is reduced. The failure rate of open-ended vasectomy is about 4% and the failure rate for NSV, 0.4%(21, 68).

Risks and complications after vasectomy

1. Acute pain and inflammation

For acute postoperative pain, NSAIDs have been shown to be superior to acetaminophen/codeine in a randomized study (7) because they block the inflammatory process. Prostaglandins participate in many genital and sexual events and mechanisms, in men, including erection, ejaculation and others. According to immunohistochemical studies, (8) nowhere in the body (specifically, the rat's body) is there a higher concentration of COX-2 receptors than in the distal vas deferens. This abundance accounts for the propensity to swelling, inflammation, scrotal edema, vasitis, and epididymitis. It occurs in 30% of men, usually around the third or fourth day postoperatively. The pain is usually minor, and settles spontaneously within a week. It can be very worrisome to the patient who was doing well until then, and may result in the misdiagnosis of infection or hematoma. Many vasectomists therefore prescribe a routine course of NSAIDs for 1 week.

2. Hematoma

Overall, reported incidences of hematoma vary from 0% to 5%, but it is unclear from study to study whether small hematomas are included, since usually no size definition is in the reports. When a significant hematoma does occur, a scrotal ultrasound and a urologist's opinion regarding advisability of drainage should be sought, despite the fact that surgical drainage is rarely recommended.

3. Infection

Infection is best defined by a requirement for an oral antibiotic or more, but the criteria are not clear in most studies, and the data is unreliable. Abscess formation is said to occur on rare occasions and may require excision or drainage. A recent case report of *Staphylococcus lugdunensis* causing endocarditis following vasectomy(9) underlines the need for vigilance despite the low risk.

4. Pain

Subacute pain, from mild to severe, intermittent to constant, is reported in 6% to 15% of post-vasectomy men. Small inflammatory masses or sperm granulomas can be associated with the pain(40). Treatment with NSAIDs is usually effective, but compliance can be

problematic. Moss noted a drop in incidence of pain, from 6% to 2%, with the change to an open-ended technique. (10)

Chronic post-vasectomy pain syndrome is said to occur in less than 1 per 1000 cases, and the cause is unknown(39). There are many features in common with other chronic pain syndromes. Treatment is in steps. Local injection, testicular denervation, excision of a painful granuloma if one exists, epididymectomy, vasectomy reversal, and orchiectomy have all been described.(11)

Vasectomy failure

In the literature, few studies define exactly what is meant by vasectomy failure in terms of sperm counts plus or minus motility, and at what point in time. Generally, the persistence of any live sperm 6 months after surgery is a reasonable indication for repeat vasectomy if the patient desires it(42).

DNA-confirmed paternity with apparent azoospermia after vasectomy has been documented with an incidence of approximately 1 in 4000. (15) In these rare cases, the intermittent appearance of small quantities of sperm through micro-canalization is postulated.

Post-vasectomy semen analysis

The 1995 CDC survey(16) points out that no consensus exists for post-vasectomy semen analysis, and no consistent practice governs the testing procedures recommended by vasectomists in the United States.(17) Testing at 6 weeks and 15 ejaculations post-op, with a retest 1 month later to identify any rare case of early recanalization. Some authorities suggest waiting 3 months to perform the first test, but longer waits tend to promote non-compliance(41). Once the occasional condom is forgotten and no pregnancy ensues, some men will wrongly assume that the vasectomy must have worked and decide, therefore, that they need not bother with testing.

Vasectomy reversal

It is estimated that approximately 6% of men who have undergone will Vasectomy subsequently request a Vasectomy reversal(45).

Criteria from Ministry of Health and Family Welfare, Govt of India:

1. Divorce and remarriage
2. Death of the only child,
3. Death of one among the 2 children, and
4. Major calamities like tsunami, flood, earth quakes.

When a man having had a vasectomy wishes to have his own biologically related children, his choices are to have a vasectomy reversal or to have sperm extraction in conjunction with IVF and ICSI. These choices plus the options of donor sperm, adoption, and remaining without children should be discussed with the couple(46). The initial consultation with the individual or couple should offer the opportunity to obtain a concise health and reproductive history of both the patient and his partner and to examine the man. Chances for success (patency or pregnancy) based on the personal experience of the surgeon, the patient's health history, and the results of examination of the man and the age and reproductive potential of his partner are discussed.

Some urologists operate using magnifying loupes, but a microsurgical repair offers the best chance for a near-flawless anastomosis, and better results. Most experienced American microsurgeons use 10-0 suture to close the vas mucosa, and add two or three more layers of closure(47).

First, scarred areas are dissected until healthy vas tissue is identified. A smear from the testicular end is checked under a microscope, looking for sperm. If absent, then the original vasectomy

probably developed leaking, scarring, and obstruction of the epididymis, commonly called a blowout.

The surgeon would then modify the procedure to a vaso-epididymostomy to get back to viable sperm. These blowouts occur progressively over time with closed-ended vasectomy procedures(49).

Preparation for vasectomy reversal

The results of microsurgical vasectomy reversal are superior to results of patency and pregnancy. Therefore, training and experience in microsurgical technique are necessary to obtain the best results in performing either vasovasostomy or vasoepididymostomy. Patency and pregnancy rates do not appear to be significantly different if a multilayer anastomosis is performed as opposed to a modified single-layer technique, but the success is physician-dependent. If vasectomy reversal done within 5 years is more successful.

Regardless of the site of vasal obstruction, certain basic principles need to be followed to optimize the chance for success. There should be sufficient mobilization of both ends of the vas deferens to prevent any tension on the anastomosis. The perivasal adventitia must remain intact. Stripping away the adventitia surrounding the cut ends of the vas risks

excising an important blood supply to the vas and may lead to ischemia and ultimate narrowing and occlusion of the anastomosis. Precise approximation of the cut lumens is mandatory to avoid sperm leakage with formation of a sperm granuloma that may disrupt the lumen and result in a failed procedure(50).

Anesthetic Considerations

Patients may prefer general anesthesia in a day surgery setting. Some men may have specific medical problems that dictate the need for a certain type of anesthesia. If the procedure is prolonged (>3 hours), the level of the patient's anxiety is high, the anatomy of the vas and epididymis is difficult to feel through a thickened or tight scrotum, or extensive vasal or epididymal mobilization is needed, a general or epidural anesthetic may be more appropriate.

Preparing the Vas for Anastomosis

With the patient supine, the vas deferens is grasped between the surgeon's thumb and forefinger above the vasectomy site. The vas is grasped with a towel clamp or vas clamp, and additional local anesthetic is injected in the skin, after which a 1- to 1.5-cm-long incision is made directly over the vas.

The vas is dissected both proximally and distally to the vasectomy site. The length of vas freed from its surrounding tissue should be sufficient to allow the freshly cut ends of the vas to slightly overlap one another once they are positioned for anastomosis. Once the vas deferens is dissected free on both sides of the vasectomy site, a towel clamp placed around the vas secures its position above the skin. The opposite side is isolated in a similar fashion. When both vasa have been dissected free, the vasa can be held with the towel clamp above skin level and held well out of the skin incision for the anastomosis by placement of 6-0 Prolene sutures through the muscular wall of each end of the vas at the level where the vas exits the skin. Some surgeons prefer to use a vas clamp rather than the suture method to hold the vas deferens in position for suturing. Whichever method is preferred, sufficient length of the vas with its associated blood supply needs to be isolated on both ends so that the surgery can be performed without tension.

The vas above and below the vasectomy site should be transected with use of the operating microscope to examine the vas; a supple, normal area of the vas is chosen to be cut and anastomosed. Once the point of the vas that is to be cut is chosen, the vasal vessels are secured with 7-0 Prolene sutures just proximal to the point of transection. After the vas is cut, the ends should be inspected and gently dilated with

forceps. No attempt is made to dilate the lumen. Progressively with lacrimal duct probes as this may tear or otherwise traumatize the delicate vaslumen. The proximal vas lumen generally is dilated and without discernible layers of muscle; on the abdominal side, the muscle groups are readily visible. A few drops of fluid from the testicular end of the vas lumen are placed on a sterile glass slide and examined by light microscopy. If there are sperm or sperm parts (sperm heads, sperm with partial tails) in large numbers or the fluid is clear and copious with no visible sperm, vaso vasostomy is generally indicated. If the fluid is thick, pasty, and devoid of sperm or contains only a few sperm heads, vasoepididymostomy should be considered.

Multilayer Vasovasostomy

Once the cut ends of the vas deferens are positioned next to one another, the anastomosis is begun by passing a 9-0 suture through the muscularis and the adventitia at the 5- and 7-o'clock positions of each side of the vas deferens. A double-armed 10-0 suture is passed through the lumen at the posterior 6-o'clock position and tied. The next sutures are placed in the wall of the lumen on either side of the first. These sutures are tied after both are in place. Three to five more sutures are placed equidistant from one another to close the remainder of the lumen but are

left untied until all the sutures have been placed. They are tied alternatively with the more lateral suture toward the one positioned at 12-o'clock. Once the anastomosis of the lumen has been completed, the 9-0 suture is again used to bring the muscularis together. A suture is placed at the 12-o'clock position first, then sequentially around the cut end of the vas until the first two sutures are reached. The adventitia is brought together over the muscularis suture line with interrupted 9-0 sutures to further enhance the blood supply at the level of the anastomosis. If a vasovasostomy is to be done on both sides, the procedure is completed on one side before the other side is approached.

Modified Single-Layer Vasovasostomy

A modified single-layer microsurgical anastomosis is as effective as the multilayer anastomosis. Some surgeons prefer this method because it is simpler, uses fewer sutures, and requires less microsurgical skill. Nevertheless, this single-layer technique should still be carried out in the same exacting fashion as the multilayer anastomosis to maximize success.

With the ends of the vas visible with the operating microscope, a double-armed 10-0 suture is passed full thickness through the edge of the proximal and distal lumen at the 6-o'clock position. Two more sutures are placed, full thickness, at the 4- and 8-o'clock positions and tied. Three

more full-thickness sutures are passed at the 10-, 12-, and 2-o'clock positions and then tied. It is important when these sutures are placed that only a small edge of the lumen be incorporated in the suture to prevent the lumen from becoming compressed and its size compromised. The anastomosis is completed by closing the muscularis and adventitia to the opposite side, placing two 9-0 sutures between each of the 10-0 full-thickness sutures.

Future trends in vasectomy

The development of the no-scalpel method of bringing the intact vas to just under the skin surface has led to an interest in other percutaneous techniques to occlude the vas lumen.

Cyanoacrylate (Dermabond) injection is widely used in China. To ensure successful cannulation, prior to blockage red dye is injected into one vas and blue into the other. When the two dyes mix, brown urine results, indicating successful cannulation bilaterally. The absence of either the red or the blue dye in the urine indicates that the vas on that side has not been successfully cannulated.(18) Cyanoacrylate did not receive approval for internal use in North America until recently, when approval was obtained in the United States for occlusion of small intracranial aneurisms.

Silicone blocking techniques and devices have been under study in various forms. One recent effort, Vasoc, was poised for investigation by the World Health Organization based on promising preliminary reports from Indonesia. The study was cancelled when a failure rate of 85% was encountered (19). Other silicone devices are also under study.

An injectable, reversible hydrogel, styrene maleic anhydrous (SMA) is currently in advanced clinical trials in India. (20) Work on other novel methods of vas occlusion is ongoing around the world.

Transcutaneous occlusion, with ultrasound or laser tissue welding, is also under investigation with good success in animal models. Ultrasonic occlusion seems to be the better technique to date (personal communication with Dr Marc Goldstein, March 2000).

OBSERVATION AND RESULTS

In the period between September 2008 to April 2011, 572 male cases involved in family planning in the form of permanent sterilization in our Kilpauk Medical College Hospital, included in this study. Most of the cases from Chennai, Thiruvallur, Chengalpet, Kancheepuram and Thiruvannamalai districts as out patients.

1. No. of patients underwent No Scalpel Vasectomy –

09/2008-2009 - 262 cases

2009-2010 - 195 cases

2010-04/2011 - 115 cases

2. Age of the patients

Majority of the males involved in this procedure are between 35-44 years of age.

Age in years	2008-2009	2009-2010	2010-2011
25-29	25	10	9
30-34	49	41	31
35-39	67	55	45
40-44	74	75	28
45-50	36	14	2
51-60	21	-	-

3. Education :

Educated patients are more understanding about the procedure and involved in the permanent male sterilization in the form of No scalpel vasectomy.

In our study group, majority of patients education between 10th and 12th std.

Education Std	2008-2009	2009-2010	2010-2011
No	7	-	-
Up to 5	37	12	6
Up to 8	44	14	15
Up to 10	72	36	22
Up to 12	37	72	41
Diploma	15	17	15
Degree	50	44	16

4. Compare with female sterilization between 2008-2011

Year	Male	Female
2008-2009	262	1900
2009-2010	195	1739
2010-2011	115	1577

5. Religion :

In our study Hindus are involved in no scalpel vasectomy procedure.

Religion	2008-2009	2009-2010	2010-2011
Hindu	218	161	103
Christian	24	17	7
Muslim	20	17	5

6. No. of living children in the family of persons involved in No Scalpel vasectomy

Year	Male children only	Female children only	Both children
2008-2009	54	47	161
2009-2010	55	54	86
2010-2011	31	27	57

Vasectomy is performed as an outpatient procedure with use of local anesthetics. The choice of local anesthetic is a 1% plain lidocaine.

The perivasal nerve block used with NSV anesthetizes a wider area, without obscuring the vas, because the perivasal nerves are blocked proximal to the operative field. First a small subcutaneous wheal is raised, and then 2 cc of local anesthetic is deposited a few centimetres above this site, along the peri vasal sheath, on both sides.

The vas deferens is separated from the spermatic cord vessels and manipulated to a superficial position under the scrotal skin. The vas is firmly trapped between the middle finger, the index finger, and the thumb of the left hand.

Grasping the vas with the ringed clamp and elevating the underlying vas.

The ring-tipped fixation clamp is grasped with the right hand and opened while pressing downward, stretching the scrotal skin tightly over the vas and locking the vas within the clamp.

The ring clamp is placed in the left hand and the trapped vas is elevated with the left index finger, tightening the scrotal skin over the vas.

A sharp-pointed, curved mosquito hemostat (introduced through the same needle puncture hole used for anesthesia) punctures the scrotal skin, vas sheath, and vas wall with one blade of the clamp.

At this point, the surrounding layers are stripped, thus exposing the bare vas. This may be accomplished by using the blades of the sharp hemostat, spreading all layers until the bare vas can be visualized. By using the right blade of the hemostat, the vas wall is skewered from inside the lumen out at a 45-degree angle and the dissecting clamp is rotated laterally 180 degrees.

Piercing the skin with the medial blade of dissecting forceps and piercing the wall of vas with tip of the lateral blade of dissecting forceps and releasing the ringed clamp and elevating the vas.

The vas is delivered through the puncture hole while the ringed fixation clamp is released. The ring clamp is used to secure the delivered vas. The sharp hemostat is used to clean the vasal vessels away from the vas, yielding a clean segment at least 2 cm in length.

The vas is then divided, and occlusion is effected by closing the fascia over one end of the cut vas (fascial interposition) to reduce the likelihood of recanalization.

After checking for bleeding, use a small hemostat to tag the vasal ends to inspect for any bleeding before returning the vas to the scrotum.

Grasping the elevated vas

Puncture the sheath and Inserting both tips of dissecting forceps into sheath and opening the forceps to strip the sheath and vasal vessels.

The contralateral vas is then approached in an identical fashion. After both vasa are returned to the scrotum, the puncture hole is pinched for a minute and inspected for bleeding. The puncture hole contracts and is virtually invisible. A sterile guaze dressing can be held in place with adhesive plaster.

7. Post vasectomy failure- 2 cases failed. The semen analysis showed 60 million in one case and 40 million in other case. Repeated analysis at 3 and 6 months showed the same results. Repeated sterilization procedure done.

8. Post vasectomy semen analysis done for all cases

9. Acute pain and inflammation

For acute postoperative pain- 15 cases.

Patients conservatively treated with NSAIDs

10.Hematoma – 2 cases. Conservatively managed.

11.Infection – no case infected

12.Chronic scrotal Pain in 3 cases.

13.Vasectomy reversal done in 6 cases within the study period.

(4cases –remarriage, 2 cases- death of the child).

DISCUSSION

Vasectomy is safer, simpler, less expensive and equally effective as female sterilization-yet it remains one of the least known and least used methods of contraception(23).

Region	Vasectomy (Millions)
Africa	0.2
Asia	22.5
Europe	2.9
North America	4.1

The use of vasectomy in the world varies. In developed countries, fewer than 5% of couples rely on vasectomy. In developing countries the prevalence of vasectomy is 2.5% (24)

Australia (2008)	11.2	China (2004)	6.7
Great Britain (2007/08)	16.0	Nepal (2006)	5.0
United states (2002)	12.8	Sri Lanka(2000)	2.1
New Zealand (1995)	19.3	India (2005/06)	1.0
Spain (1999)	9.0	Bangladesh(2006)	0.6

The most recent estimate from 2007 suggests that vasectomy users has dropped to 33 million whereas the number of female sterilization users remained at 225 million(65)

In India there is a definite bias towards prevalence of female methods of contraception over male methods. According to National Family Health Survey (NFHS) II data, 42.2 percent of the women reported the use of any female modern method as against only 9.0 percent of using any male method.

States	2006-07	2007-08
Gujarat	1032	20,646
West Bengal	1828	18,352
Bihar	1134	6,238
Orissa	790	2605
Punjab	5615	11,048
Delhi	1320	3,467

Table presents the percentage distribution of the use of contraception by men. Among the major states the use of any modern male method is highest in Punjab, followed by Haryana, and then Maharashtra and Gujarat. It is lowest in the southern state of Karnataka. Sterilization is highest in Punjab, followed by Maharashtra and then by Kerala. The percentage is lowest in Karnataka and second lowest in Uttar Pradesh and low in Bihar and Tamil Nadu.

States	Male sterilization in percentage
Bihar	1.7
Punjab	15.6
Karnataka	1.7
Kerala	5.6
Tamil Nadu	2.3
Our study	5.37

Sterilization of males is highest in Punjab followed by Kerala and it is lowest in Karnataka. The use of sterilization has dropped in all states.

Effectiveness of vasectomy techniques

1. Contraceptive effectiveness (absence or occurrence of pregnancy)
2. Occlusive effectiveness (semen analysis)

In Contraceptive effectiveness, pregnancy is the endpoint. It would be difficult to conduct during prospective studies. Therefore success rate of no scalpel vasectomy based on semen analysis data.

Post vasectomy semen analysis usually recommended at 12 weeks. The reason for delayed testing is to allow time for men who have slow clearance to reach azoospermia.

In our cases there are 2 cases showed sperm count of 40 million/ml and 60 million/ml after 12 weeks.

Post vasectomy Recanalization of the vas

Reasons:

1. Granulomatous reaction bridges the gap between the cut ends.
2. Epithelial lined microtubules producing the fistula.
3. Spontaneous recanalization (denovo).
4. Technical failure(one vas not occluded).
5. An anatomical variation(duplicate vas).

Simple excision and ligation, surgical clips associated with high risk of failure. Fascial interposition reduce the risk of failure. According to the Indian Council of medical Research, the current Government recommended technique in India is ligation and excision combined with Fascial interposition. In all of our cases done with Fascial Interposition.

Surgical technique	Reported failure rate
Cautery and excision	< 4.8%
Fascial interposition	< 1.2%
Ligation and excision	1.5 to 29%
Open testicular end and fascial interposition	0.02 to 2.4%

Complications

1. Hematoma and Infection.

Hematoma is the most common complication of vasectomy, with an average incidence of 2% (Kendrick et al, 1987). The hematoma rate was significantly higher among physicians performing 1 to 10 vasectomies (4.6%) than among those performing 11 to 50 vasectomies (2.4%) or more than 50 vasectomies (1.6%) per year(39). In our study Hematoma occurs in 0.3% cases.

Study	No.of vasectomy	%with infection	%with hematoma
Nirapathpongporn, &Krieger,1990	680	0.2	0.3
Li et al,1991	238	0	0
Kumar et al, 1999	4253	0.047	0.03
Sokal et al., 1999	606	0.2	1.7
Our study	572	0	0.3

Sperm Granuloma.

Sperm granulomas(46) form when sperm leak from the testicular end of the vas. Sperm are highly antigenic, and an intense inflammatory reaction occurs when sperm escape outside the reproductive epithelium.(47) Sperm granulomas are rarely symptomatic. The presence or absence of a sperm granuloma at the vasectomy site seems to be of importance in modulating the local effects of chronic obstruction on the male reproductive tract. The sperm granuloma's complex network of epithelialized channels provides an additional absorptive surface that helps vent the high intraluminal pressure in the obstructed ducts. Although sperm granulomas at the vasectomy site are present microscopically in 10% to 30% of men undergoing reversal, it is likely, given enough time, that virtually all men develop sperm granulomas at

the vasectomy site, the epididymis, or the rete testis(47,48,49). In our study, all the 6 cases operated for vasectomy reversal, sperm granuloma present at vasectomy site.

Long-term Effects

Vasitis nodosa, chronic testicular or epididymal pain, alterations in testicular function, chronic epididymal obstruction(40).

Outcomes:

Level I evidence indicates that the no-scalpel method is generally preferred over the conventional technique for fewer complications but it appears more difficult for physicians to learn. In a Cochrane database review, Cook *et al.* evaluated 2 randomized controlled trials comparing the scalpel and no-scalpel incisions for vasectomy. Fascial interposition was noted to reduce surgical failure.

No scalpel vasectomy training programs:

As the first country introducing NSV technique, Thailand hopes NSV will become the standard vasectomy procedure, which may then promote the acceptability of vasectomy. Between November 1986 and June 1989, 13 Thai PDA physicians performed NSV in 6238 cases, Surgeons at the Ramathibodi hospital, who attended the 1st International training course in Bangkok in 1986, have had a total of 1500-2000 NSV acceptors (Nirapathpongporn A *et al*, unpublished data, 1989).

Ramathibodi hospital started to provide a 3-day NSV training course for 13 Thai physicians from the provincial hospitals in 1987. Since then the demand for the training increased, and the training centre had to be moved to a regional hospital in the next two years, where a sufficient case load for 100 trainees would be available.

The first training course was organized by that hospital in March 1992, and the NSV procedure was thus officially introduced into India. Based on the data of the hospital, after the use of NSV, the number of vasectomy increased three times as compared with the corresponding period in 1988-91. The no-scalpel vasectomy attracted more educated and higher income men although in India the acceptability of vasectomy is influenced by religious factors.

Developing countries

According to the International Planned Parenthood Federation, AVSC is now assisting in training more than 5000 physicians in twenty-five developing countries,

In our Kilpauk Medical College Hospital, Chennai conducts No-Scalpel Vasectomy weekly three days camp under National Health and Family welfare, Govt. of India, from March 2009- October 2010.

CONCLUSION

Men often play the dominant roles in decisions crucial to reproductive health of women. However, family planning programs and policies often assume that men take minimal interest in matters that concern reproduction. The National Population Policy, 2000 India underscores the need to facilitate increased participation of men in Planned Parenthood. It aims at popularizing male methods of contraception

The Advantage of No-Scalpel Vasectomy

A one-time, relatively inexpensive cost that is often covered by state grant programs

- More dependable than any other form of birth control
- Less expensive and poses less of a medical risk than female sterilization
- Easier to reverse than female sterilization
- Eliminates risks to female partner of oral contraceptives or IUDs
- Most common age group involved in No-Scalpel Vasectomy is between 35- 45 years.
- Male involvement in family planning is gradually increasing compare to female participation in family planning.

- Educated males more involved in NSV.
- Hindus are more voluntarily involved in the family planning procedure in the form of NSV
- No-scalpel approach resulted in less bleeding, hematoma, infection, and pain, as well as shorter operative times.
- Fascial interposition was noted to reduce surgical failure in all of our cases.
- Vasectomy reversal done in 6 cases in this study period (loss of child in 2 men, and remarriage in 4 men).

Raising the skin wheal and creating vasal block

Isolating right vas.

Isolating left vas

Vas fixation clamp and Dissecting forceps

Instruments for no-scalpel vasectomy

Grasping the vas with the ringed clamp and elevating the underlying vas.

Piercing the skin with the medial blade of dissecting forceps and piercing the wall of vas with tip of the lateral blade of dissecting forceps and releasing the ringed clamp and elevating the vas.

The vas is delivered through the puncture hole while the ringed fixation clamp is released. The ring clamp is used to secure the delivered vas. The sharp hemostat is used to clean the vasal vessels away from the vas, yielding a clean segment at least 2 cm in length.

The vas is then divided, and occlusion is effected by closing the fascia over one end of the cut vas (fascial interposition) to reduce the likelihood of recanalization.

After checking for bleeding, use a small hemostat to tag the vasal ends to inspect for any bleeding before returning the vas to the scrotum.

Grasping the elevated vas.

Puncture the sheath and Inserting both tips of dissecting forceps into sheath and opening the forceps to strip the sheath and vasal vessels.

Prostatic end of the vas ligated

Prostatic and Testicular end ligated.

Up to 1cm vas excised

Both ends are separated by at least 1cm

Gently pinches and pulls up on the scrotum with the thumb and index finger. The prostatic end of the vas is pulled through the puncture wound

The fascial membrane is tied 2-3mm below the tie at the prostatic end. The stump at the prostatic end is allowed to slip back into the scrotum.

After completion of procedure
